SonaKhata

“every gram, on record for both sides”

The Problem:

Jewellers across India hand gold worth lakhs to karigars, the artisans who make the jewellery, and the only record is usually one line in the jeweller's notebook. The karigar has no copy, wastage is agreed verbally, and at month end it becomes one person's word against the other's. The record exists, but it belongs to only one side.

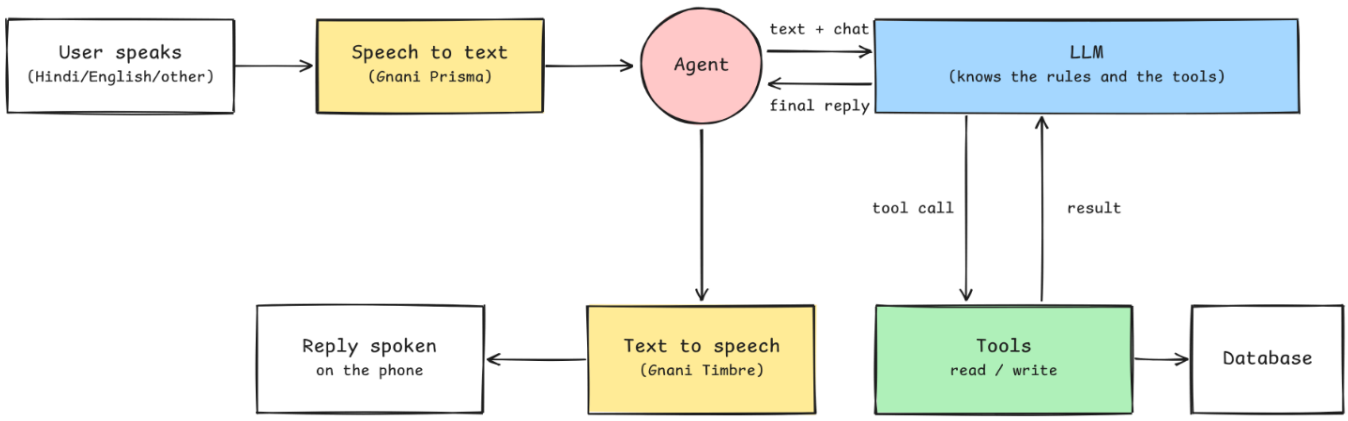

The Solution:

SonaKhata is a voice-first, AI-powered shared gold ledger that brings jewellers and karigars onto a single, mutually verified record. Instead of writing entries by hand, users simply speak in Hindi, English or other Indian languages. An AI agent understands the instruction, extracts the details, reads them back for approval, and creates the entry only after the user confirms. Every gold movement follows a two-sided confirmation process: the other party can confirm or reject an entry with a reason. This applies to extra gold issued, partial returns and final deliveries. Only entries confirmed by both parties become locked records, preventing either side from independently changing or deleting an agreed transaction.

SonaKhata automatically tracks gold issued, gold returned, agreed wastage, pending orders, delivery deadlines and labour dues. It calculates the final gold account using only mutually confirmed entries, giving both parties a transparent view of every transaction. Designed for real jewellery workshops, its voice-based interface makes it accessible to users with limited literacy and those who prefer speaking over typing. Secure login ensures each user accesses only their own records, while a complete audit trail preserves who created and confirmed every entry.

SonaKhata replaces one-sided notebooks and verbal agreements with a shared, transparent and mutually trusted gold ledger.

The AI Agent Architecture:
